

On measures in independent fields*

Edited by S. Hartman

Among the papers left by Banach was found the incomplete Polish manuscript of this paper, written in 1940. § 1 is almost literally translated from the manuscript. The details of farther reasonings were elaborated by S. Hartman, who also supplied the paper with Appendices and adapted it for print, with some help of Henry Helson.

§ 1. Let T be an arbitrary space. A family \mathfrak{R} of fields ⁽¹⁾ of subsets of T is said to be a family of *independent* fields if any finite number of non-empty sets, belonging to different fields of \mathfrak{R} , has a non-empty intersection. That is, \mathfrak{R} is an independent family if the conditions $0 \neq H_i \in A_i \in \mathfrak{R}$ and $A_i \neq A_j$ for $i \neq j$ ($i, j = 1, \dots, n$) always imply

$$\prod_{i=1}^n H_i \neq 0.$$

The family \mathfrak{R} is called a family of *denumerably independent* fields if any sequence of non-empty sets, belonging to different fields of \mathfrak{R} , has a non-empty intersection; i.e. if $0 \neq H_i \in A_i \in \mathfrak{R}$ and $A_i \neq A_j$ for $i \neq j$ ($i, j = 1, 2, \dots$) always imply $\prod_{i=1}^{\infty} H_i \neq 0$.

The concept of independence of fields of sets was introduced by Marczewski ⁽²⁾, who also proved the following theorem ⁽³⁾:

* Commenté sur p. 363.

⁽¹⁾ The class \mathcal{A} of subsets of a space T is called a *field* if \mathcal{A} contains with any set its complement and with any finite number of sets their sum. The field \mathcal{A} is a *Borel field* if the sum of any denumerable number of sets of \mathcal{A} belongs to \mathcal{A} .

⁽²⁾ Cf. E. Marczewski, *Indépendance d'ensembles et prolongement de mesures (Résultats et problèmes)*, Colloquium Mathematicum 1 (1948), p. 122-132, especially p. 125-127.

⁽³⁾ Ibidem, Théorème II, p. 126-127. For the proof of this theorem see Marczewski [6].

Let \mathfrak{R} be a family of independent fields with a measure ⁽¹⁾ μ defined in each field $A \in \mathfrak{R}$, and let $U(\mathfrak{R})$ be the smallest field containing all the fields of \mathfrak{R} . Then a measure μ^* can be defined in $U(\mathfrak{R})$ with the following properties:

$$(I) \quad \mu^*(H) = \mu(H) \quad \text{if } H \in A \in \mathfrak{R},$$

(II) $\mu^*\left(\prod_{i=1}^n H_i\right) = \prod_{i=1}^n \mu^*(H_i)$ if $H_i \in A_i \in \mathfrak{R}$, $A_r \neq A_s$ for $r \neq s$ and n a natural number not greater than the power of \mathfrak{R} (which can be finite)⁽²⁾.

Marczewski has asked whether the following theorem is true ⁽³⁾:

THEOREM 1. Let \mathfrak{R} be a family of denumerably independent Borel fields with a denumerably additive measure μ defined in each field $A \in \mathfrak{R}$; then a denumerably additive measure μ^* can be defined in the smallest Borel field containing all the fields of \mathfrak{R} , such that:

$$(1) \quad \mu^*(H) = \mu(H) \quad \text{if } H \in A \in \mathfrak{R},$$

$$(2) \quad \mu^*\left(\prod_{i=1}^{\infty} H_i\right) = \prod_{i=1}^{\infty} \mu^*(H_i) \quad \text{if } H_i \in A_i \in \mathfrak{R}, \text{ and } A_i \neq A_j \text{ for } i \neq j$$

($i, j = 1, 2, \dots$).

The object of this paper is to answer the question affirmatively.

Theorem 1 was proved by Marczewski in the special case that every field $A \in \mathfrak{R}$ contains just four sets ⁽⁴⁾, viz. a set H , its complement, the empty set, and T . Then evidently every $A \in \mathfrak{R}$ is a Borel field and any measure μ defined in A is denumerably additive. The theorem was enunciated by P. Lévy in another special case, namely when \mathfrak{R} consists of two fields and the measures have a special form ⁽⁵⁾.

§ 2. The smallest (finitely additive) field containing all the fields of \mathfrak{R} will be denoted, as above, by $U(\mathfrak{R})$. To prove Theorem 1 it is enough

⁽¹⁾ A measure μ in a field A is a real function $\mu(H) \geq 0$ defined for every set $H \in A$, such that $\mu(T) = 1$ and $\mu(H_1 + H_2) = \mu(H_1) + \mu(H_2)$ for any disjoint $H_1, H_2 \in A$. The measure is denumerably additive if $\mu\left(\sum_{i=1}^{\infty} H_i\right) = \sum_{i=1}^{\infty} \mu(H_i)$ for disjoint $H_1, H_2, \dots \in A$.

⁽²⁾ Fields A_i for which condition (II) holds are said to be *stochastically independent* with respect to the measure μ^* .

to define a measure μ^* in $U(\mathfrak{R})$ satisfying (1), (2) and the following condition:

(3) If $H_i \in U(\mathfrak{R})$ ($i = 1, 2, \dots$) are disjoint and if $\sum_{i=1}^{\infty} H_i \in U(\mathfrak{R})$, then

$$\mu^* \left(\sum_{i=1}^{\infty} H_i \right) = \sum_{i=1}^{\infty} \mu^*(H_i).$$

For then it is known that μ^* can be extended to a denumerably additive measure on the smallest Borel field over $U(\mathfrak{R})$, i.e. the smallest Borel field containing all the fields of \mathfrak{R} .

Moreover, (3) can be replaced by the equivalent condition:

(4) If $H_i \in U(\mathfrak{R})$, $H_i \supset H_{i+1}$ ($i = 1, 2, \dots$) and $\lim_{i \rightarrow \infty} \mu^*(H_i) > 0$, then

$$\prod_{i=1}^{\infty} H_i \neq 0.$$

Let $F[U(\mathfrak{R})]$ be the family of all real functions defined for $t \in T$, assuming only a finite number of values, each value being assumed on a set belonging to $U(\mathfrak{R})$. Every function $y \in F[U(\mathfrak{R})]$ can be written in the following form (see Appendix I):

$$(5) \quad y(t) = \sum a_{k_1 \dots k_m} \prod_{j=1}^m z_{jk_j}(t).$$

Here the $z_{jk}(t)$ are the characteristic functions of non-empty sets Z_{jk} , which belong to different fields $A_j \in \mathfrak{R}$ for different j , and which are disjoint in k for any field j . That is:

- (α) $Z_{jk} \neq 0$,
- (β) $Z_{jk} \in A_j \in K$, $A_i \neq A_j$ for $i \neq j$,
- (γ) $Z_{jk} \cdot Z_{jl} = 0$, for $k \neq l$ and $j = 1, 2, \dots, m$.

The coefficients $a_{k_1 \dots k_m}$ are real numbers, and the summation is extended over all systems $k_1 \dots k_m$ which satisfy the conditions $1 \leq k_j \leq r_j$ ($j = 1, \dots, m$).

§ 3. Uniformization. Let y_1 and y_2 be two (not necessarily different) functions from $F[U(\mathfrak{R})]$. They are said to be *uniformized* when they are written

$$(6) \quad y_1(t) = \sum a_{k_1 \dots k_m}^{(1)} \prod_{j=1}^m z_{jk_j}(t),$$

$$(7) \quad y_2(t) = \sum a_{k_1 \dots k_m}^{(2)} \prod_{j=1}^m z_{jk_j}(t),$$

where the $z_{jk}(t)$ are the characteristic functions of sets Z_{jk} which satisfy conditions (α) - (γ) . The summations in (6) and (7) are extended over the same systems of indices $k_1 \dots k_m$ ($1 \leq k_j \leq r_j$). Thus the right sides of (6) and (7) can differ only in the coefficients $a_{k_1 \dots k_m}$.

Refinement. Let y be a function given in the form (5), and let $\mathbf{B}_1, \mathbf{B}_2, \dots, \mathbf{B}_p$ ($p \geq m$) be distinct fields of \mathfrak{R} , among which occur the \mathbf{A}_j . For each j suppose s_j non-empty disjoint sets $U_{ji} \in \mathbf{B}_j$ are given such that if \mathbf{B}_j is identical with some \mathbf{A}_i , then every Z_{jk} is the sum of some of the U_{ji} , and if \mathbf{B}_j is different from all the \mathbf{A}_i , the sum of the U_{ji} is T .

Then (5) can be transformed (see Appendix II, 1°) into the following:

$$(8) \quad y(t) = \sum_{i_1 \dots i_p} b_{i_1 \dots i_p} \prod_{j=1}^p u_{ji_{i_j}}(t) \quad (1 \leq i_j \leq s_j),$$

where $u_{ji}(t)$ is the characteristic function of U_{ji} . We call (8) a *refinement* of (5) by the sets U_{ji} .

For two functions (not necessarily different) from $F[U(\mathfrak{R})]$ given in the form (5), there always exists (see Appendix III) a system of sets U_{ji} by which both functions can be refined. Such a common refinement uniformizes the functions. Hence *any two functions of $F[U(\mathfrak{R})]$ can be uniformized*.

Denumerable uniformization. If y_n is a sequence of functions belonging to $F[U(\mathfrak{R})]$, in general no uniformization is possible for all y_n in the sense defined above.

However, the following representation can always be reached (see Appendix IV):

$$(9) \quad y_n(t) = \sum a_{k_1 \dots k_{m_n}}^{(n)} \prod_{j=1}^{m_n} z_{jk_j}^{(n)}(t) \quad \text{for } n = 1, 2, \dots,$$

where $z_{jk}^{(n)}$ is the characteristic function of a non-empty set $Z_{jk}^n \in \mathbf{B}_j \in \mathfrak{R}$, with the sequence $\{\mathbf{B}_j\}$ (generally infinite) containing no field more than once. The numbering of the \mathbf{B}_j is determined simultaneously for all n . Further, as usual, $Z_{jr}^n \cdot Z_{js}^n = 0$ for $r \neq s$, and the summation in (9) is taken over all systems $k_1 \dots k_{m_n}$ such that $1 \leq k_j \leq r_j^{(n)}$. In general, the sequence m_n is unbounded as n increases. The sequence y_n , given in the form (9), is said to be *denumerably uniformized*.

§ 4. LEMMA 1. *Let two uniformized functions y_1 and y_2 of $F[U(\mathfrak{R})]$ be given:*

$$y_1(t) = \sum a_{k_1 \dots k_m}^{(1)} \prod_{j=1}^m z_{jk_j}(t), \quad y_2(t) = \sum a_{k_1 \dots k_m}^{(2)} \prod_{j=1}^m z_{jk_j}(t).$$

If for every t we have $y_1(t) = y_2(t)$ or $y_1(t) \geq y_2(t)$, then for every set of indices we have $a_{k_1 \dots k_m}^{(1)} = a_{k_1 \dots k_m}^{(2)}$ or $a_{k_1 \dots k_m}^{(1)} \geq a_{k_1 \dots k_m}^{(2)}$ respectively.

Proof. If we set $a_{k_1 \dots k_m}^{(1)} - a_{k_1 \dots k_m}^{(2)} = a_{k_1 \dots k_m}$, then

$$\sum a_{k_1 \dots k_m} \prod_{j=1}^m z_{jk_j}(t) = 0 \text{ or } \geq 0, \text{ resp., for all } t.$$

From conditions (α) and (β) and from the independence of the fields of \mathbb{R} it follows that for every system of indices $\sigma_1, \dots, \sigma_m$ there is a $t \in T$ for which $\prod_{j=1}^m z_{j\sigma_j}(t) = 1$.

From (γ) , $\prod_{j=1}^m z_{jk_j}(t) = 0$ for the same t and any other system $k_1 \dots k_m$.

So for this t ,

$$\sum a_{k_1 \dots k_m} \prod_{j=1}^m z_{jk_j}(t) = a_{\sigma_1 \dots \sigma_m}$$

and $a_{\sigma_1 \dots \sigma_m} = 0$ or ≥ 0 , according as $y_1(t) = y_2(t)$ or $y_1(t) \geq y_2(t)$ for all t . Since the set $\sigma_1 \dots \sigma_m$ was arbitrary, the lemma is proved.

Remark. Only the finite independence of the fields of \mathbb{R} was used in the proof; their denumerable independence will be used later.

LEMMA 2. If $y(t) \geq 0$, or $= 0$, or ≤ 0 for all t , then for every system of indices, $a_{k_1 \dots k_m} \geq 0$, or $= 0$, or ≤ 0 respectively.

This is an immediate consequence of Lemma 1.

§ 5. We now introduce three operations on the functions $y \in F[U(\mathbb{R})]$, called integration, contraction and separation.

Integration. If y is given by (5), write formally

$$\int_T y(t) dt = \sum a_{k_1 \dots k_m} \prod_{j=1}^m \mu Z_{jk_j}.$$

We show that the integral does not depend on the particular representation of y (always, of course, of the same type as (5)). Indeed, suppose

$$(10) \quad y(t) = \sum b_{k_1 \dots k_p} \prod_{j=1}^p v_{jk_j}(t),$$

where the $v_{jk}(t)$ are the characteristic functions of sets V_{jk} . Let U_{ji} be a system of sets which refines both representations, yielding

$$y(t) = \sum c_{k_1 \dots k_q}^{(1)} \prod_{j=1}^q u_{jk_j}(t), \quad y(t) = \sum c_{k_1 \dots k_q}^{(2)} \prod_{i=1}^q u_{ik_i}(t)$$

respectively, where u_{jk} is the characteristic function of U_{jk} . By Lemma 1, $c_{k_1 \dots k_q}^{(1)} = c_{k_1 \dots k_q}^{(2)}$ for every set of indices; by Appendix II, 2°⁽¹⁾ the integral is not changed by refinement. That is,

$$\begin{aligned} \sum a_{k_1 \dots k_m} \prod_{j=1}^m \mu(Z_{jk_j}) &= \sum c_{k_1 \dots k_q}^{(1)} \prod_{j=1}^q \mu(U_{jk_j}) \\ &= \sum c_{k_1 \dots k_q}^{(2)} \prod_{j=1}^q \mu(U_{jk_j}) = \sum b_{k_1 \dots k_p} \prod_{j=1}^p \mu(V_{jk_j}), \end{aligned}$$

which establishes the invariance of the definition.

Let y_1 and y_2 be functions from $F[U(\mathfrak{R})]$, with uniformized representations

$$y_1(t) = \sum a_{k_1 \dots k_m}^{(1)} \prod_{j=1}^m u_{jk_j}(t), \quad y_2(t) = \sum a_{k_1 \dots k_m}^{(2)} \prod_{j=1}^m u_{jk_j}(t).$$

It is immediate that

$$(11) \quad \int_T (y_1(t) + y_2(t)) dt = \int_T y_1(t) dt + \int_T y_2(t) dt,$$

$$(12) \quad \int_T ay(t) dt = a \int_T y(t) dt$$

for any number a . By Lemma 2,

$$(13) \quad \int_T y(t) dt \geq 0 \quad \text{if} \quad y(t) \geq 0 \quad \text{for all } t.$$

Denote by $F(\mathcal{A})$ the subset of $F[U(\mathfrak{R})]$ composed of all functions which assume each of their values in a set belonging to $\mathcal{A} \in \mathfrak{R}$, and let $y(t) \in F(\mathcal{A})$. The representation (5) becomes then

$$y(t) = \sum_{k=1}^m a_k z_k(t),$$

and the corresponding integral is $\sum_{k=1}^m a_k \mu(Z_k)$; this integral is identical with that in customary sense engendered by the measure μ . Hence follows

$$(14) \quad \int_T 1 dt = \mu(T) = 1,$$

the function $y(t) = c$ being contained in all sets $F(\mathcal{A})$.

⁽¹⁾ Only finite additivity of the measure μ is assumed there. Denumerable additivity will be required later.

From (11) and (13) it follows that

$$(15) \quad \text{if } y_1(t) \geq y_2(t) \text{ for all } t, \text{ then } \int_T y_1(t) dt \geq \int_T y_2(t) dt.$$

Finally suppose $U \in \mathbf{A} \in \mathfrak{R}$, $V \in \mathbf{B} \in \mathfrak{R}$, and let u, v be the characteristic functions of U, V resp. By the definition of the integral,

$$(16) \quad \int_T u(t) \cdot v(t) dt = \mu(U) \cdot \mu(V).$$

Contraction. Given $y(t) = \sum a_{k_1 \dots k_m} \prod_{j=1}^m z_{jk_j}(t)$, define:

$$(17) \quad W(y, t) = \sum a_{k_1 \dots k_m} z_{1k_1}(t) \prod_{j=2}^m \mu Z_{jk_j}, \quad \text{if } m \geq 2,$$

$$(18) \quad W(y, t) = y(t) \quad \text{if } m = 1.$$

We call (17) the *contraction* of y with respect to the field \mathbf{A}_1 . The result of the operation evidently depends on the choice of \mathbf{A}_1 ; however, a proof entirely analogous to that given for integration and in Appendix II shows that $W(y, t)$ is not changed by refinement of y , and it follows that the definition does not depend on the representation of y , once \mathbf{A}_1 has been fixed. Exactly as for the integral one proves that contraction by a given field is a linear operation, and that if $y(t) \geq 0$ for all t , the same is true of $W(y, t)$. Hence

$$(19) \quad \text{if } y_1(t) \geq y_2(t) \text{ for all } t, \text{ then } W(y_1, t) \geq W(y_2, t) \text{ for all } t,$$

where contraction is performed with respect to the same field.

Separation. Again suppose $y(t) = \sum a_{k_1 \dots k_m} \prod_{j=1}^m z_{jk_j}(t)$. For any $t_1 \in T$ define

$$(20) \quad S(y, t_1, t) = \sum a_{k_1 \dots k_m} z_{1k_1}(t_1) \prod_{j=2}^m z_{jk_j}(t).$$

We call this operation *separation* performed at t_1 with respect to the field \mathbf{A}_1 . Again it is easy to show that $S(y, t_1, t)$ depends only on y, t_1, t and \mathbf{A}_1 , and not on the representation of y once \mathbf{A}_1 has been fixed. For fixed t_1 and \mathbf{A}_1 , separation is a linear operation; and if y is non-negative, so is $S(y, t_1, t)$. Hence

$$(21) \quad \text{if } y_1(t) \geq y_2(t) \text{ for all } t, \text{ then } S(y_1, t_1, t) \geq S(y_2, t_1, t) \text{ for all } t, t_1,$$

where separation is performed with respect to the same field.

LEMMA 3. *If y is of the form (5), then*

$$\int_T S(y, t_1, t) dt = W(y, t_1) \quad \text{and} \quad \int_T W(y, t) dt = \int_T y(t) dt.$$

These relations are evident on writing out the integrals explicitly.

§ 6. Measure. Let E belong to $U(\mathfrak{R})$, with characteristic function y . Define

$$(22) \quad \mu^*(E) = \int_T y(t) dt.$$

It follows from (11) and (13) that μ^* is a (finitely additive) measure, and by the definition of the integral we have $\mu^*(E) = \mu(E)$ for $E \in \mathcal{A} \in \mathfrak{R}$. By (16) the fields $\mathcal{A} \in \mathfrak{R}$ are stochastically independent with respect to μ^* . So μ^* satisfies the conditions of the theorem of Marczewski. Since only the hypotheses of that theorem have been used, we have proved it on the way to the main result.

§ 7. LEMMA 4. *Let y be of form (5), a a real number, and t_1, \dots, t_m points of T such that*

$$Y(t_1, \dots, t_m) \stackrel{\text{def}}{=} \sum a_{k_1 \dots k_m} \prod_{j=1}^m z_{jk_j}(t_j) \geq a.$$

Then there are sets $H_j \in \mathcal{A}_j$ ($j = 1, \dots, m$) for which

$$(23) \quad t_j \in H_j,$$

$$(24) \quad y(t) \geq a \quad \text{for all} \quad t \in \prod_{j=1}^m H_j.$$

Proof. First assume that $t_j \in \sum_{k=1}^{r_j} Z_{jk}$ for each j ; that is, there are indices $\sigma_1, \dots, \sigma_m$ for which $t_j \in Z_{j\sigma_j}$. Let $H_j = Z_{j\sigma_j}$. Evidently $H_j \in \mathcal{A}_j$, so it remains to prove (24). Notice that $k_j \neq \sigma_j$ implies $t_j \notin Z_{jk_j}$, or $z_{jk_j}(t_j) = 0$, so $Y(t_1, \dots, t_m) = a_{\sigma_1 \dots \sigma_m}$; hence $a_{\sigma_1 \dots \sigma_m} \geq a$. Now if $t \in \prod_{j=1}^m H_j$, we have also $y(t) = a_{\sigma_1 \dots \sigma_m} \geq a$.

Now suppose $t_j \notin \sum_{k=1}^{r_j} Z_{jk}$ for at least one j , say for $j = s_1, \dots, s_p$ ($1 \leq p \leq m$). For each such j , $z_{jk}(t_j) = 0$ ($k = 1, \dots, r_j$), so that $\prod_{j=1}^m z_{jk_j}(t) = 0$ for any indices k_1, \dots, k_m . Hence $Y(t_1, \dots, t_m) = 0$ and $a \leq 0$. Set $H_j = T - \sum_{k=1}^{r_j} Z_{jk}$ for $j = s_1, \dots, s_p$, and $H_j = \sum_{k=1}^{r_j} Z_{jk}$ for other j . Then

$t_j \in H_j \in \mathcal{A}_j$. If $t \in \prod_{k=1}^m H_j$, then $t \notin Z_{jk}$ ($k = 1, \dots, r_j$) for at least one j (since $p \geq 1$), from which $\prod_{j=1}^m z_{jk_j}(t) = 0$ for any choice of the k_j . Hence $y(t) = 0 \geq a$, and (24) holds.

LEMMA 5. Let $y_n(t) = \sum a_{k_1 \dots k_m}^{(n)} \prod_{j=1}^m z_{jk_j}^{(n)}(t)$ be a sequence of denumerably uniformized functions from $F[U(\mathfrak{R})]$; suppose there is a finite or infinite sequence t_1, t_2, \dots of elements of T , such that for each n

$$Y_n(t_1, \dots, t_{m_n}) \geq a.$$

Then there is some $\vartheta \in T$ for which $y_n(\vartheta) \geq a$ ($n = 1, 2, \dots$).

Proof. By Lemma 4, for each n there are sets $H_j^n \in \mathcal{A}_j$ ($j = 1, \dots, m_n$) with the properties:

$$t_j \in H_j^n \quad \text{for } j = 1, \dots, m_n,$$

$$y_n(t) \geq a \quad \text{for } t \in \prod_{j=1}^{m_n} H_j^n.$$

For $j > m_n$ set $H_j^n = T$ and define $W_j = \prod_{j=1}^{\infty} H_j^n$. Each W_j is non empty, since $t_j \in W_j$; and because the $\mathcal{A} \in \mathfrak{R}$ are Borel fields (the first use of this hypothesis), $W_j \in \mathcal{A}_j$. Now set $H = \prod_{j=1}^{\infty} W_j$. This intersection is non-empty, because the $\mathcal{A} \in \mathfrak{R}$ are denumerably independent (this is the only use of the hypothesis in the proof!). But if $\vartheta \in H$, then $\vartheta \in \prod_{j=1}^{m_n} H_j^n$ and $y_n(\vartheta) \geq a$ for all n . So the lemma is proved.

§ 8. Proof of Theorem 1. It only remains to prove that μ^* satisfies condition (4). Suppose

$$H_n \in U(K), \quad H_n \supset H_{n+1}, \quad \mu^*(H_n) \geq a > 0, \quad n = 1, 2, \dots$$

Let y_n be the characteristic function of H_n . Then $y_n \in F[U(K)]$, $\int_T y_n(t) dt \geq a$, and for all t

$$(25) \quad y_n(t) \geq y_{n+1}(t) \quad (n = 1, 2, \dots).$$

We take the y_n denumerably uniformized:

$$y_n(t) = \sum a_{k_1 \dots k_{m_n}}^{(n)} \prod_{j=1}^{m_n} z_{jk_j}^{(n)}(t).$$

Then

$$(26) \quad m_{n+1} \geq m_n \quad (n = 1, 2, \dots).$$

By (19), for all t

$$(27) \quad W(y_n, t) \geq W(y_{n+1}, t) \quad (n = 1, 2, \dots),$$

and by Lemma 3

$$(28) \quad \int_T W(y_n, t) dt \geq a \quad (n = 1, 2, \dots).$$

Now every $W(y_n, t)$ belongs to $F(\mathcal{A}_1)$. But μ^* is in \mathcal{A}_1 a denumerably additive measure (this is the first use of the hypothesis), and the integral of $y_n(t)$ over T (in the sense given p. 279) is an integral generated by μ^* in the Lebesgue sense. Hence, applying (28),

$$(29) \quad \int_T \lim_{n \rightarrow \infty} W(y_n, t) dt = \lim_{n \rightarrow \infty} \int_T W(y_n, t) dt \geq a.$$

By (27) and (29) there is an element t_1 for which

$$(30) \quad W(y_n, t_1) \geq a \quad (n = 1, 2, \dots).$$

Now set $y_{n,1}(t) = S(y_n, t_1, t)$. These functions are already denumerably uniformized. By (21), $y_{n,1}(t) \geq y_{n+1,1}(t)$ for all t ; by (30) and Lemma 3

$$\int_T y_{n,1}(t) dt \geq a \quad (n = 1, 2, \dots).$$

So the $y_{n,1}$ are like the y_n , and there is a t_2 for which

$$W(y_{n,1}, t_2) \geq a \quad (n = 1, 2, \dots),$$

where contraction is performed with respect to \mathcal{A}_2 . Setting $y_{n,2}(t) = S(y_{n,1}, t_2, t)$, we have $y_{n,2}(t) \geq y_{n+1,2}(t)$ for all t and

$$\int_T y_{n,2}(t) dt \geq a \quad (n = 1, 2, \dots).$$

This procedure can be repeated indefinitely by setting

$$y_{n,k+1}(t) = S(y_{n,k}, t_{k+1}, t).$$

If $m_n = l$ for some n (or several, or infinitely many n), say for n such that $p \leq n \leq r$, we have for these n after the $(l-1)^{\text{th}}$ step

$$(31) \quad y_{n,l-1}(t) = \sum a_{k_1 \dots k_l}^{(n)} \cdot z_{lk_l}^{(n)}(t) \prod_{j=1}^{l-1} z_{jk_j}^{(n)}(t_j).$$

The functions $y_{n,l-1}$ with $p \leq n \leq r$ each belongs to $F(A_l)$. Contraction with respect to A_l leaves by (18) the $y_{n,l-1}$ invariant. Having fixed l , the $W(y_{n,l-1}, t)$ is a non-increasing sequence in the index n , and for every n

$$\int_T W(y_{n,l-1}, t) dt \geq a.$$

It follows that there is a t_l such that

$$W(y_{n,l-1}, t_l) \geq a \quad (n = 1, 2, \dots)$$

and in particular

$$(32) \quad y_{n,l-1}(t_l) \geq a \quad \text{for} \quad p \leq n \leq r.$$

For these values of n , however, the left side of (32) is by (31), on one hand, the function $y_{n,l}(t) = S(y_{n,l-1}, t_l, t)$, which is a constant, and, on the other hand, identical with $Y_n(t_1, \dots, t_{m_n})$.

In case $m_n = l$ for all $n \geq p$, the process is finished; otherwise continue with those $y_{n,l}(t)$ for which $m_n > l$, in other words, for which $n > r$. Finally, a (possibly finite) sequence of elements t_1, t_2, \dots is at hand, which with the y_n satisfy the hypothesis of Lemma 5.

So there is a $\vartheta \in T$ for which $y_n(\vartheta) \geq a$ ($n = 1, 2, \dots$). Since $a > 0$ and the y_n are characteristic functions, $y_n(\vartheta) = 1$, so that $\vartheta \in H_n$ ($n = 1, 2, \dots$).

Hence $\prod_{n=1}^{\infty} H_n \neq 0$, (4) is shown, and Theorem 1 is proved.

APPENDIX I

Representation of functions

Let H_ν ($\nu = 1, \dots, p$) be sets belonging to $U(\mathfrak{R})$. For every ν

$$(1) \quad H_\nu = \sum_{i=1}^{n_\nu} \prod_{j=1}^{m_{\nu i}} G_{ij}^\nu,$$

where each set G_{ij}^ν belongs to a field $A_{ij}^\nu \in \mathfrak{R}$, with $A_{ir}^\nu \neq A_{is}^\nu$ if $r \neq s$. Renumber the fields A_{ij}^ν in simple order: A_1, \dots, A_m , where distinct indices belong to distinct fields. In each intersection of (1) write the factors G_{ij}^ν in the order of the indices of the fields to which they belong, supplying a T as the r^{th} factor if no G_{ij}^ν belongs to A_r ($\nu = 1, \dots, m$). By the independence of the fields, no set except 0 and T can belong to more

than one field, so this rearrangement can be carried out without ambiguity. By renaming the reordered factors we have a representation

$$(2) \quad H_\nu = \sum_{i=1}^{n_\nu} \prod_{j=1}^m H_{ij}^\nu,$$

where $H_{ij}^\nu \in \mathbf{A}_j \in \mathfrak{R}$ ($\mathbf{A}_r \neq \mathbf{A}_s$ for $r \neq s$).

Now for each j put the sets H_{ij}^ν in a simple series H_{jk} ($k = 1, \dots, s_j$; $H_{jk} \neq H_{jl}$ for $k \neq l$). For each j and every system $\sigma_1 \dots \sigma_{s_j}$ composed of zeros and ones, form the product

$$\prod_{k=1}^{s_j} (-1)^{\sigma_k} H_{jk},$$

where $-H_{jk}$ means $T-H_{jk}$.

Suppose r_j of these intersections are non-void; call them Z_{jk} ($k = 1, \dots, r_j$). Evidently $Z_{jk} \in \mathbf{A}_j$, $Z_{jk} \cdot Z_{jl} = 0$ for $k \neq l$, and every H_{ij}^ν is the sum of some of the sets Z_{j1}, \dots, Z_{jr_j} . So there are numbers β_{ijk}^ν (each 0 or 1) such that

$$H_{ij}^\nu = \sum_{k=1}^{r_j} \beta_{ijk}^\nu Z_{jk}.$$

Setting this in (2) we obtain

$$H_\nu = \sum_{i=1}^{n_\nu} \sum_{k_1 \dots k_m} [\beta_{i1k_1}^\nu \dots \beta_{imk_m}^\nu \prod_{j=1}^m Z_{jk_j}],$$

where the outer summation is taken over all systems $k_1 \dots k_m$ ($1 \leq k \leq r_j$).

Setting $a_{k_1 \dots k_m}^\nu$ equal to the smaller value of 1 and $\sum_{i=1}^{n_\nu} \beta_{i1k_1}^\nu \dots \beta_{imk_m}^\nu$, we get

$$(3) \quad H_\nu = \sum a_{k_1 \dots k_m}^\nu \prod_{j=1}^m Z_{jk_j}.$$

The intersections in (3) are disjoint.

Let Z_{jk} be the characteristic function of Z_{jk} , and y_ν the characteristic function of H_ν . Then

$$(4) \quad y_\nu(t) = \sum a_{k_1 \dots k_m}^\nu \prod_{j=1}^m z_{jk_j}(t).$$

Now if $y \in F[U(\mathfrak{R})]$ assumes its values $\alpha_1, \dots, \alpha_p$ on the sets H_1, \dots, H_p respectively, $y(t) = \sum_{v=1}^p \alpha_v y_v(t)$, i.e.

$$y(t) = \sum a_{k_1 \dots k_m} \prod_{j=1}^m z_{jk_j}(t),$$

where the summation is taken over systems $k_1 \dots k_m$ ($1 \leq k_j \leq r_j$), and

$$a_{k_1 \dots k_m} = \sum_{v=1}^p \alpha_v a_{k_1 \dots k_m}^v.$$

APPENDIX II

Refinement

1° Let the function y be given in the form

$$(1) \quad y(t) = \sum a_{k_1 \dots k_m} \prod_{j=1}^m z_{jk_j}(t),$$

where each z_{jk} is the characteristic function of a non-empty set $Z_{jk} \in A_j \in \mathfrak{R}$ ($1 \leq k \leq r_j$), with $A_r \neq A_s$ for $r \neq s$; and $Z_{jk} \cdot Z_{jl} = 0$ for any j , when $k \neq l$.

Let $B_1, B_2, \dots, B_m, \dots, B_p$ be distinct fields of \mathfrak{R} , such that $B_i = A_i$ for $i \leq m$. Suppose further we are given sets $U_{ji} \in B$, non-empty, disjoint in i for fixed j , and such that for $j \leq m$

$$(2) \quad Z_{jk} = \sum_{i=1}^{s_j} \beta_{jki} U_{ji} \quad (\text{each } \beta_{jki} \text{ being either 0 or 1}),$$

and for $j > m$

$$(3) \quad T = \sum_{i=1}^{s_j} \beta_{j1i} U_{ji} \quad (\text{each } \beta_{j1i} = 1).$$

If u_{ji} is the characteristic function of U_{ji} ,

$$(4) \quad \sum_{i=1}^{s_j} \beta_{jki} u_{ji}(t) = z_{jk}(t) \quad \text{when } j \leq m,$$

$$(5) \quad \sum_{i=1}^{s_j} \beta_{j1i} u_{ji}(t) = 1 \text{ for all } t, \quad \text{when } j > m.$$

Write unit factors in each product of (1) so the index j runs from 1 to p , and then substitute formulas (4) and (5) for the functions z_{jk_j} and for the unit factors respectively. Then we have

$$\begin{aligned}
 (6) \quad y(t) &= \sum a_{k_1 \dots k_m} \prod_{j=1}^p \sum_{i=1}^{s_j} \beta_{jk_j i} u_{ji}(t) \\
 &= \sum a_{k_1 \dots k_m} \sum \beta_{1k_1 i_1} \dots \beta_{pk_p i_p} \prod_{j=1}^p u_{ji_j}(t),
 \end{aligned}$$

where the inner summation is taken over all sets $i_1 \dots i_p$ such that $1 \leq i_j \leq s_j$ for each j , and the outer summation as before over sets k_1, \dots, k_m such that $1 \leq k_j \leq r_j$. Changing the order of summation and writing

$$(7) \quad b_{i_1 \dots i_p} = \sum_{k_1 \dots k_m} a_{k_1 \dots k_m} \beta_{1k_1 i_1} \dots \beta_{pk_p i_p},$$

we have

$$y(t) = \sum_{i_1 \dots i_p} b_{i_1 \dots i_p} \prod_{j=1}^p u_{ji_j}(t).$$

This representation is a refinement of (1) by the sets U_{ji} .
 2° We show that

$$(8) \quad \sum a_{k_1 \dots k_m} \prod_{j=1}^m \mu(Z_{jk_j}) = \sum b_{i_1 \dots i_p} \prod_{i=1}^p \mu(U_{ji_j}).$$

Indeed, from (2)

$$(9) \quad \mu(Z_{jk}) = \sum_{i=1}^{s_j} \beta_{jki} \mu(U_{ji}) \quad \text{for } j \leq m,$$

and from (3)

$$(10) \quad 1 = \sum_{i=1}^{s_j} \beta_{j1i} \mu(U_{ji}) \quad \text{for } j > m.$$

By the same algebraic procedure as before, i.e. by writing $p-m$ unit factors in each product on the left side of (8), and by substituting (9) and (10), we obtain

$$\sum a_{k_1 \dots k_m} \sum \beta_{1k_1 i_1} \dots \beta_{pk_p i_p} \prod_{i=1}^p \mu(U_{ji_j}),$$

where the sums are as in (6). By changing the order of summation and using (7) the right side of (8) appears.

APPENDIX III

Common refinement

Let functions y_1 and y_2 of $F[U(\mathfrak{R})]$ be given, not necessarily distinct:

$$(1) \quad y_1(t) = \sum a_{k_1 \dots k_{m_1}}^{(1)} \prod_{j=1}^{m_1} z_{jk_j}^{(1)}(t),$$

$$(2) \quad y_2(t) = \sum a_{k_1 \dots k_{m_2}}^{(2)} \prod_{j=1}^{m_2} z_{jk_j}^{(2)}(t).$$

Here the $z_{jk}^{(\nu)}$ are characteristic functions of sets Z_{jk}^ν ($\nu = 1, 2$; $j = 1, \dots, m_\nu$; $k = 1, \dots, r_j^{(\nu)}$), such that $Z_{jk}^\nu \neq 0$, $Z_{jk}^\nu \in \mathcal{A}_j^\nu \in \mathfrak{R}$ ($\mathcal{A}_r^\nu \neq \mathcal{A}_s^\nu$ for $r \neq s$), and $Z_{jr}^\nu \cdot Z_{js}^\nu = 0$ if $r \neq s$. There may or may not be fields \mathcal{A}_i^1 identical with fields \mathcal{A}_j^2 . But form a series $\mathbf{B}_1, \dots, \mathbf{B}_\rho$ out of the \mathcal{A}_i^1 and the \mathcal{A}_j^2 which includes each field just once, and for each of the \mathbf{B}_j , renumber in a series Z_{js} ($s = 1, \dots, \rho_j$) all the sets Z_{rk}^ν such that $\mathcal{A}_r^\nu = \mathbf{B}_j$. As in Appendix I form all the intersections

$$(3) \quad \prod_{s=1}^{\rho_j} (-1)^{\sigma_s} Z_{js},$$

where the σ_s assume the values 0, 1; and number the non-void intersections U_{j1}, \dots, U_{js_j} . Evidently for each j , $U_{ji} \in \mathbf{B}_j$ and $U_{ji} \cdot U_{jk} = 0$ if $i \neq k$; each set Z_{ik}^ν belonging to \mathbf{B}_j is the sum of some of the U_{ji} , and for fixed j the sum of the U_{ji} is T . Thus the sets U_{ji} yield a common refinement of (1) and (2).

APPENDIX IV

Denumerable uniformization

Let a sequence of functions from $F[U(\mathfrak{R})]$ be given:

$$(1) \quad y_n(t) = \sum b_{i_1 \dots i_{p_n}}^{(n)} \prod_{j=1}^{p_n} u_{ji}^{(n)}(t),$$

where $u_{ji}^{(n)}(t)$ is the characteristic function of a non-empty set

$$U_{ji}^n \in \mathcal{A}_j^n \in \mathfrak{R} \quad \text{for} \quad n = 1, 2, \dots; \quad j = 1, \dots, p_n; \quad i = 1, \dots, s_j^{(n)}.$$

If $r \neq s$, $\mathcal{A}_r^n \neq \mathcal{A}_s^n$ and $U_{jr}^n \cdot U_{js}^n = 0$. We shall transform (1) by induction so as to obtain a representation of the following kind:

$$(2) \quad y_n(t) = \sum a_{k_1 \dots k_{m_n}}^{(n)} \prod_{j=1}^{m_n} z_{jk_j}^{(n)}(t),$$

where $z_{jk}^{(n)}(t)$ is the characteristic function of a set $Z_{jk}^n \neq 0$, $Z_{jk}^n \in \mathbf{B}_j \in \mathfrak{R}$ for $n = 1, 2, \dots$; $j = 1, \dots, m_n$; $i = 1, \dots, r_j^{(n)}$; if $r \neq s$, $\mathbf{B}_r \neq \mathbf{B}_s$ and $Z_{jr}^n Z_{js}^n = 0$. Here the sequence $\{\mathbf{B}_j\}$ does not involve the index n .

Assume that y_1, \dots, y_{n-1} are already expressed in the form (2), with the fields $\mathbf{B}_1, \dots, \mathbf{B}_{m_{n-1}}$ and the sets $Z_{jk}^l \in \mathbf{B}_j$ determined ($l = 1, \dots, n-1$; $j = 1, \dots, m_{n-1}$; $k = 1, \dots, r_j^{(l)}$).

1° If a field A_j^n is identical with \mathbf{B}_n for some $h \leq m_{n-1}$, set $U_{jk}^n = Z_{hk}^n$, and accordingly

$$u_{jk}^{(n)}(t) = z_{hk}^{(n)}(t), \quad s_j^{(n)} = r_h^{(n)}.$$

2° If there are fields A_j^n which are not among the \mathbf{B}_i ($i = 1, \dots, m_{n-1}$), denote them by $\mathbf{B}_{m_{n-1}+1}, \dots, \mathbf{B}_{m_n}$, and write correspondingly:

$$\begin{aligned} U_{jk}^n &= Z_{m_{n-1}+1k}^n, \dots, Z_{m_n k}^n, \\ u_{jk}^{(n)}(t) &= z_{m_{n-1}+1k}^{(n)}(t), \dots, z_{m_n k}^{(n)}(t) \quad (1 \leq k \leq s_j^{(n)}), \\ s_j^{(n)} &= r_{m_{n-1}+1}^{(n)}, \dots, r_{m_n}^{(n)}. \end{aligned}$$

3° If some \mathbf{B}_j ($j \leq m_{n-1}$) does not occur among the A_j^n , set

$$Z_{j1}^n = T, \quad z_{j1}^{(n)}(t) = 1 \quad \text{for all } t, \text{ and } r_j^{(n)} = 1.$$

By this procedure each product

$$(3) \quad \prod_{j=1}^{p_n} u_{ji_j}^{(n)}(t)$$

of (1) is transformed into a product

$$(4) \quad \prod_{j=1}^{m_n} z_{jk_j}^{(n)}(t),$$

which differs from (3) only in the order of the factors and the presence of certain unit factors. Bearing in mind that $r_j^{(n)} = 1$ for the j considered in 3°, each $b_{i_1 \dots i_{p_n}}^{(n)}$ can be rewritten $a_{k_1 \dots k_{m_n}}^{(n)}$, and y_n has been reduced to form (2).
